

"From Robustness to Antifragility: A Philosophical Perspective on Climate and Earth System Models"

Ryan O'Loughlin
Department of Philosophy
roloughlin@qc.cuny.edu

Prologue

- Why care what a philosopher has to say: **shared goal (kind of)**
- Methodological similarities: **both look at empirical evidence**
- Methodological differences:
 - **modeling and computing vs. scientific-practice-as-evidence**
 - **differences in specialized terminology**

Key take-away points

1. *Convergence between climate models can be informally confirmatory (model robustness)*
2. *Failures in modeling can provide opportunities to yield new knowledge (model antifragility)*

Conclusions and Implications

General Circulation Models (GCMs)

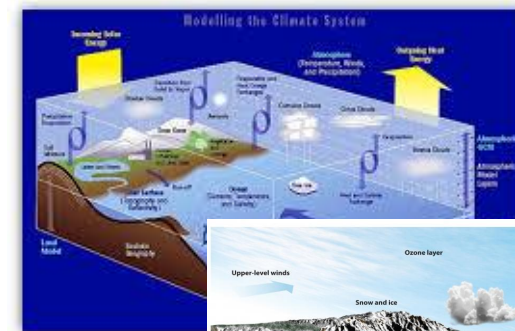

Same earth

Same core physics

Different models = different renderings with the same core

Process reps vary (but some are shared)

Resolutions vary

InsideClimate News

Model intercomparisons: continuity of a research strategy

- Atmospheric (1990s): 31 modeling groups, 31 distinct models

- Coupled (sixth phase; today): 49 modeling groups; 100 distinct models

National flag circles mark over 100 climate modeling groups — including the NASA Goddard Institute for Space Studies (GISS) — contributing to the Coupled Model Intercomparison Project Phase 6 (CMIP6). Google Map by CMIP6

Typical framing...

Hypothesis of interest: under a high-emissions scenario, global mean surface temperature will be 4°C warmer in the 2060s compared to the 1960s

Question: does the (mere) fact that the models agree lend additional support to the hypothesis?

Question: does the (mere) fact that the models agree lend additional support to the hypothesis?

- **Maybe yes, because these different models are all getting the same answer**
- **But maybe no, because the models are not independent from each other:**
 - Shared code (shared lineage)
 - Shared personnel
 - Model ensembles are “ensembles of opportunity” (Tebaldi and Knutti 2007)
 - Some errors and biases are common to most/all models

- **Question: does the fact that the models agree lend support to the hypothesis?**
- **New question: when models converge, is there a basis for strengthened confidence (in the models or their result)?**

Model robustness framing:

- i. Models are of a shared **model type**
- ii. Models within type have some **different idealizations** with evidential support for each
- iii. When models converge, there is often a **key causal process** involved, and the credibility of this causal process can be evaluated

Model robustness

Case study

Enhanced summer convective rainfall at Alpine high elevations in response to climate warming

Filippo Giorgi^{1*}, Csaba Torma¹, Erika Coppola¹, Nikolina Ban², Christoph Schär² and Samuel Somot³

Model-type: regional climate models, all simulating a high-emissions scenario

Different idealizations: models used different convective parameterizations (evidential support = aircraft data, satellite data, higher resolution simulations)

Key causal process: reduction in 500 hPa and 850hPa potential temperatures differences (plus Clausius Clapeyron), and evapotranspiration, leading to more convective precipitation; deemed credible

- New question: When models converge, is there a basis for strengthened confidence (in the models or their result)?
- In Giorgi et al. case: Yes, finding that each model shared the same core causal mechanism (a mechanism that is credible) **informally confirms the model-type.** This is especially so given the evidential support for the models' idealizations etc. Thus, our confidence in these models is strengthened.

Conclusions and Implications

Q1. Does explanation increase our confidence? If so, how?

What is the probability of not throwing double sixes?

(1/36)

(1/36)

(1/36)

(15/36)

(1)

(1)

$$1 - \left(\frac{1}{36} \times \frac{3}{6} + \frac{15}{36} \times \frac{1}{6} + 1 \times \frac{2}{6} \right) = 1 - \frac{15}{36} = \frac{21}{36}$$

Q1. Does explanation increase our confidence? If so, how?

What is the probability of not throwing double sixes?

(1/36)

(1/36)

(15/36)

(1)

(1)

$$1 - \frac{15}{36} = \frac{21}{36}$$

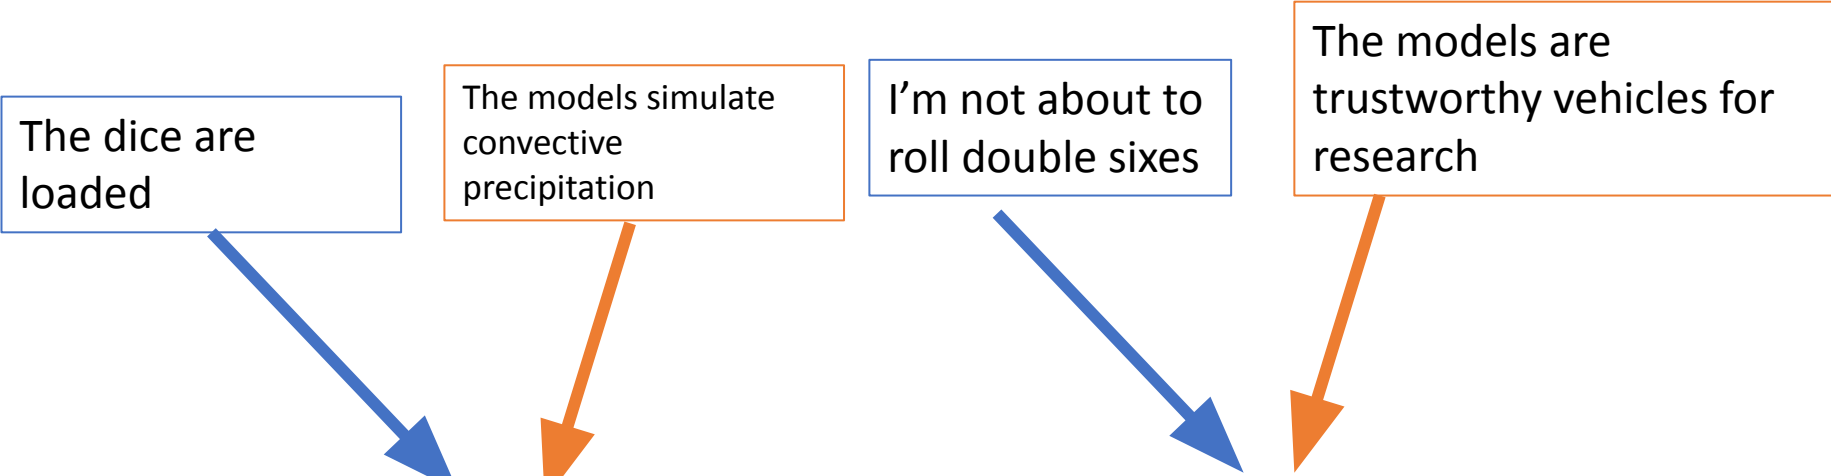

Credit for thought experiment goes to: Gimbel, S., 1999. Peirce snatching: Towards a more pragmatic view of evidence. Erkenntnis, 51(2), pp.207-231.

The dice are loaded

The models simulate convective precipitation

I'm not about to roll double sixes

The models are trustworthy vehicles for research

Knowing the causal mechanism enhances belief through explanation rather than probability adjustment.

Convergence and model robustness

Informal confirmation

Failures and Antifragility

Example: Historical Constraints

Conclusions and Implications

All models are wrong (George Box 1976)

- One interpretation:

- Models *inevitably* idealize and abstract
 - Parameterizations
 - Any difference b/w model and real world
 - E.g., discrete (15 min) time-steps in simulation

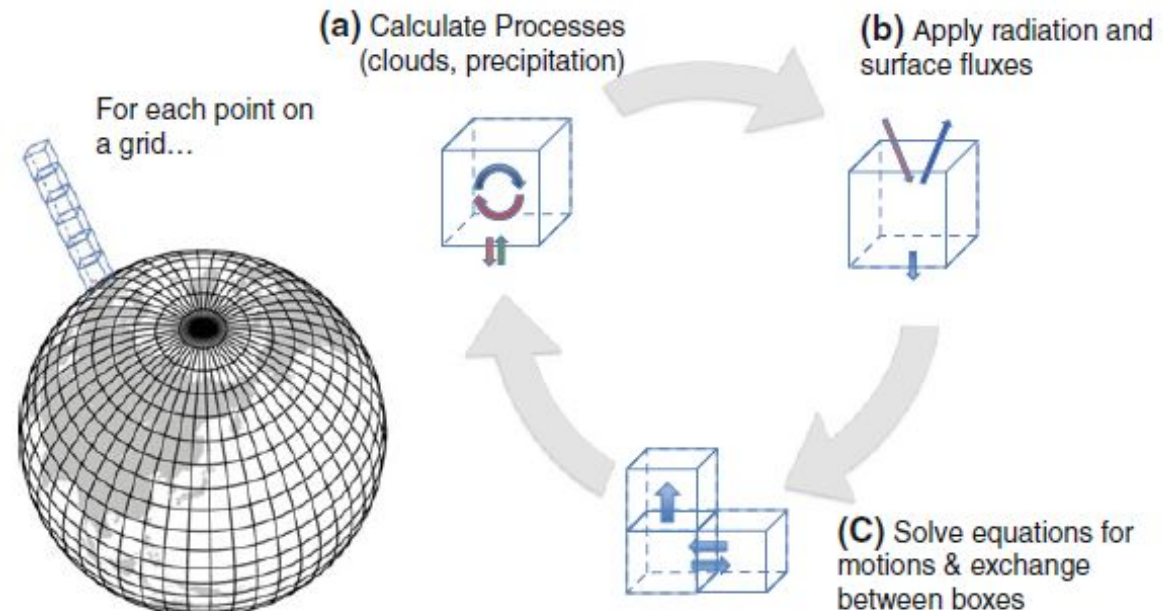

All models are wrong (George Box 1976)

- One interpretation:

- Models *inevitably* idealize and abstract
 - Parameterizations
 - Any difference b/w model and real world
 - E.g., time-steps in simulation

- **Another** interpretation:

- All models produce output that is inaccurate
 - Or at least: all models produces at least some output that is inaccurate

Performance

- A modeling endeavor is **fragile** □ sensitive to assumptions, models unproductively disagree, conclusions are undermined
- A modeling endeavor is **robust** □ insensitive to assumptions, models with same causal core agree on many conclusions
- A modeling endeavor is **antifragile** □ sensitive to assumptions, models productively disagree, new knowledge can be produced through apparent “failures”

Conclusions and Implications

Key take-away points

1. *Convergence between climate models can be informally confirmatory (model robustness)*
2. *Failures in modeling can provide opportunities to yield new knowledge (model antifragility)*

Lingering questions

1. Can we give a formal account of how climate model convergence is confirmatory?
2. What are the different types of antifragility in scientific modeling and how can antifragility be enhanced in research practices?
3. Does the use of AI/ML in climate science render research **less** antifragile?

Thank you!

I look forward to any feedback and comments!
